Getting Started with [moduleName] API

The [moduleName] API enables [frontEndName] with storage-as-a-service.

In this guide, you'll learn how to request an access token and make a simple API call.

1. Prerequisites

Complete the following items before continuing with this guide:

- Get a program to make requests, such as Postman (preferred) or Insomnia.
- Request access to the AD group `resource.name`.

2. Create an OAuth Application

This section shows how to create an OAuth Application with the required scopes for the API authorization mechanisms.

1. Go to your OAuth Apps
2. Create a new OAuth app with the following custom scopes:
    - `resource.action::create:`
    - `resource.action::read:`
    - `resource.action::update:`
    - `resource.action::delete:`

3. Request an Access Token

This section shows how to generate an access token for the API.

3.1 [authenticationService] Domains

The [appName] leverages [authenticationService] credentials to authenticate requests.

Find the host URL based on the development environment of your choice:

[authenticationService] Domain	Host
Prod	`https://example.prod/v1/token`
QA	`https://example.qa/v1/token`
Dev	`https://example.dev/v1/token`

3.2 Query Parameters

The host URL accepts the following query parameters:

- **`client`**: Specifies the application client.
- **`secret`**: Specifies the application's environment secret.
- **`type`**: Specifies the authentication method.
- **`scope`**: Specifies the request method type for your access token.

3.2.1 Get client

1. Go to OAuth Application

1. Go to OAuth Applications
2. Copy the value from the "client" column associated to the OAuth Application that you created on step 2.
3. Paste the value on the `client` query parameter.

3.2.2 Get secret

1. Go to AD Dashboard.
2. Under Applications, Select [appName]
3. Copy the value `secret`
4. Paste the value on the `secret` query parameter.

3.2.3 Get type

Enter "`client_credentials`".

3.2.4 Get scope

1. Go to OAuth Applications.
2. Click on the OAuth Application that you created on step 2.
3. Under **Custom Scopes**, copy one or more scopes for your access token.

> NOTE
>
> The authorization type variable locates at the end of the scope string, example:
>
> ```
> resource.action::scope:
> _________________^^^^^^_
> ```

4. Paste the value on the `scope` query parameter.

3.3 Query the Host

This is an example to request a QA read access token:

> POST
>
> ```
> https://example.com/v1/token?client=[client]&secret=[secret]&type=client_credentials&scope=plat
> ```

This is the structure of the query:

- Host: `https://example.com.com`
- Endpoint: `/v1/token`
- Query Parameters: `?client=[client]&secret=[secret]&type=client_credentials&scope=app.global::read:`
- Content-Type: `application/x-www-form-urlencoded`

Replace the variables from the query parameters with the data from step 3.2.

This is an example of the access token:

```
{
    "token_type": "Bearer",
    "expires_in": 3600,
    "access_token": {yourAccessToken},
    "scope": "{scope1} {scope2} ... {scopeN}"
}
```

```
}
```

To see more details about your access token, use a tool like jwt.io.

4. Stack Mapping

The [appName]] GraphQL API deploys in:

Stack	Backend URL	CDN URL
PROD		
UAT	`https://asd.example.com/graphql`	`https://uat.some.place/api/graphQL`
STG	`https://qwe.example.com/graphql`	`https://stg.some.place/api/graphQL`
QA	`https://wer.example.com/graphql`	`https://qa.some.place/api/graphQL`
DEV	`https://sdf.example.com/graphql`	`https://dev.some.place/api/graphQL`

> **NOTE**
>
> The URLs might change in newer release versions, if you're having issues visit the Changelog.

5. Request Sample Query

Follow the steps to request a sample query:

1. Go to Postman or Insomnia
2. Create a new POST request
3. Enter a URL from the Stack Mapping table.
4. Enable bearer authentication and enter your `access_token`.
5. Enter the following data in Query:

```
mutation DeletePetMutation(
   $petId: ID!
   $requestedBy: String!
   $confirmationCode: Int!
   ) {
   deletePet(
      petId: $petId
      requestedBy: $requestedBy
      confirmationCode: $confirmationCode
   )
}
```

6. Enter the following Graphql variables:

```
{
   "petId": "12345",
   "requestedBy": "user@example.com",
   "confirmationCode": 67890
}
```

7. Submit the request, you must see a confirmation response:

Good work, you're ready to explore the API reference.
