

Explanation

This page explains how development teams use PaaS components to integrate their data models with platform capabilities.

Use Cases

PaaS supports two main use cases:

A. Author an application

Instantiate an application for a data model with built-in platform capabilities.

“[\[Application 1\]](#), [\[Application 2\]](#), and [\[Application 3\]](#) are examples of fully built PaaS applications.

B. Extend functionality to an existing application

Integrate platform capabilities to an existing application.

“[\[Application 4\]](#) is an example of an enhanced application.

PaaS Components

PaaS comprises three main components:

- **Data Model**

PaaS adapts platform capabilities to your data model. To learn about the data model requirements, check the [PaaS How-To Guide](#)

- **Platform Application Template**

PaaS offers a quick setup through its application template, comprising a catalog of easy-to-integrate modular backend components known as technical capabilities. For more information, see the section, "[capabilities](#)".

- **Platform Tools**

Platform Tools is the SDK that brings speed to software development. By leveraging the Data Model and Platform Application Template, teams create platform applications quickly and simply.

The following diagram shows the PaaS components serving both use cases:

Figure 1. PaaS System Context

Capabilities

PaaS offers a collection business and technical capabilities.

Business Capabilities

Existing PaaS applications exposing merchandising data:

Business Capability	Description
[Application 2]	Lorem ipsum dolor sit amet.
[Application 3]	Lorem ipsum dolor sit amet.
[Application 4]	Lorem ipsum dolor sit amet.

Technical Capabilities

Technical capabilities are backend capabilities enabling platform applications with standardized data processing mechanisms:

Figure 2. Platform capabilities

Available capabilities for platform applications:

Core Capability	Description	Available to Existing Applications
Ingestion	Provides mechanisms for ingesting data from various sources.	Yes
API Authoring	Enables Dev teams to develop interfaces for managing the platform application's data.	
Search APIs	Allow users to query the platform application's data.	Yes
Observability	Provides Dev teams with monitoring tools to supervise the platform application's performance.	Yes
Global Distribution	Distributes the platform application data across multiple geographic regions.	Yes
Storage	Enables data producers with CRUD storage-as-a-service.	
Cache	Enables temporary storage for faster data access.	Yes
Streaming	Enables near-real-time platform application data processing and transmission.	Yes
Security	Ensures platform application data integrity and confidentiality.	Yes
Authorization	Enables Dev teams to manage and control the platform application data movement within the	Yes

Access/Manage	Enables user access to manage and control the platform application data and content within the system.	Yes
Controls		
Data Backups	Ensures regular backups of platform application data to prevent data loss.	Yes
Disaster Recovery	Provides mechanisms and procedures for restoring platform application data and functionality.	Yes
